

STEPBYSTEP-FINAL-EasyVisa

March 22, 2025

Artificial Intelligence and Machine Learning

Advanced Machine Learning - Project Debrief

Visa Approval Facilitation

0.1 Problem Statement

0.1.1 Context:

Business communities in the United States are facing high demand for human resources, but one of the constant challenges is identifying and attracting the right talent, which is perhaps the most important element in remaining competitive. Companies in the United States look for hard-working, talented, and qualified individuals both locally as well as abroad.

The Immigration and Nationality Act (INA) of the US permits foreign workers to come to the United States to work on either a temporary or permanent basis. The act also protects US workers against adverse impacts on their wages or working conditions by ensuring US employers' compliance with statutory requirements when they hire foreign workers to fill workforce shortages. The immigration programs are administered by the Office of Foreign Labor Certification (OFLC).

OFLC processes job certification applications for employers seeking to bring foreign workers into the United States and grants certifications in those cases where employers can demonstrate that there are not sufficient US workers available to perform the work at wages that meet or exceed the wage paid for the occupation in the area of intended employment.

0.1.2 Objective:

In FY 2016, the OFLC processed 775,979 employer applications for 1,699,957 positions for temporary and permanent labor certifications. This was a nine percent increase in the overall number of processed applications from the previous year. The process of reviewing every case is becoming a tedious task as the number of applicants is increasing every year.

The increasing number of applicants every year calls for a Machine Learning based solution that can help in shortlisting the candidates having higher chances of VISA approval. OFLC has hired the firm EasyVisa for data-driven solutions. You as a data scientist at EasyVisa have to analyze the data provided and, with the help of a classification model:

- Facilitate the process of visa approvals.
- Recommend a suitable profile for the applicants for whom the visa should be certified or denied based on the drivers that significantly influence the case status.

0.1.3 Data Description

The data contains the different attributes of employee and the employer. The detailed data dictionary is given below.

- `case_id`: ID of each visa application
- `continent`: Information of continent the employee
- `education_of_employee`: Information of education of the employee
- `has_job_experience`: Does the employee has any job experience? Y= Yes; N = No
- `requires_job_training`: Does the employee require any job training? Y = Yes; N = No
- `no_of_employees`: Number of employees in the employer's company
- `yr_of_estab`: Year in which the employer's company was established
- `region_of_employment`: Information of foreign worker's intended region of employment in the US.
- `prevailing_wage`: Average wage paid to similarly employed workers in a specific occupation in the area of intended employment. The purpose of the prevailing wage is to ensure that the foreign worker is not underpaid compared to other workers offering the same or similar service in the same area of employment.
- `unit_of_wage`: Unit of prevailing wage. Values include Hourly, Weekly, Monthly, and Yearly.
- `full_time_position`: Is the position of work full-time? Y = Full Time Position; N = Part Time Position
- `case_status`: Flag indicating if the Visa was certified or denied

2   education_of_employee                 25480 non-null  object
3   has_job_experience                     25480 non-null  object
4   requires_job_training                 25480 non-null  object
5   no_of_employees                       25480 non-null  int64
6   yr_of_estab                           25480 non-null  int64
7   region_of_employment                 25480 non-null  object
8   prevailing_wage                       25480 non-null  float64
```

```

9    unit_of_wage                25480 non-null object
10   full_time_position          25480 non-null object
11   case_status                 25480 non-null object
dtypes: float64(1), int64(2), object(9)
memory usage: 2.3+ MB

```

Observations: Based on the `data.info()` output, here are several key observations about this dataset:

Size: The dataset contains 25,480 records (rows) across 12 columns. Completeness: There are no missing values in any column, as indicated by all columns having “25,480 non-null” counts. Data types:

Most columns (9) are of type “object” which in pandas typically represents string/categorical data 2 columns are integers (int64): “no_of_employees” and “yr_of_estab” 1 column is floating-point (float64): “prevailing_wage”

Content: This appears to be employment or visa-related data, likely concerning:

Job applications or work permits across different continents/regions Information about employee education, experience, and training requirements Details about employers (establishment year, number of employees) Wage information and employment terms (full-time or not) Case statuses, possibly approval/rejection decisions

Potential analysis directions:

The “case_status” column likely contains the outcome variable (approved/denied) Several categorical predictors could influence case outcomes Wage data could be analyzed by region, education level, etc. The dataset appears suitable for classification modeling to predict case outcomes

```

25477   False
25478   False
25479   False
Length: 25480, dtype: bool

```

0.5 Exploratory Data Analysis (EDA)

Let’s check the statistical summary of the data

```

[ ]: data.describe().T ## Complete the code to print the statistical summary of the
    ↪ data

```

```
[ ]:
      count      mean      std      min      25%  \
no_of_employees 25480.0  5667.043210 22877.928848 -26.0000 1022.00
yr_of_estab     25480.0  1979.409929  42.366929 1800.0000 1976.00
prevailing_wage 25480.0 74455.814592 52815.942327   2.1367 34015.48

      50%      75%      max
no_of_employees 2109.00  3504.0000 602069.00
yr_of_estab     1997.00  2005.0000  2016.00
prevailing_wage 70308.21 107735.5125 319210.27
```

Observations: For no_of_employees:

Count: 25,480 (all rows) Mean: ~5,667 employees Std: ~22,878 (very high standard deviation) Min: -26 (confirming the negative values we found earlier) 25%: ~1,022 employees 50% (median): ~2,109 employees 75%: ~3,504 employees Max: 602,069 employees (extremely large)

For yr_of_estab (year of establishment):

Range from 1800 to 2016 Median is around 1997, suggesting many relatively newer companies 75% of companies were established after around 1976

For prevailing_wage:

Extremely wide range (min appears very low, max over \$210,000) Mean of approximately \$74,456 Median around \$60,000-70,000 (estimated from the poorly formatted output)

Key observations:

Extreme skew in company size: The massive difference between median (~2,109) and maximum (602,069) employees indicates a few very large corporations among mostly smaller or medium businesses. Potential data quality issues: The negative employee counts need to be addressed. Wide wage distribution: The large standard deviation in wages suggests significant variation by position, location, or other factors. Company age diversity: You have companies ranging from very old (established in 1800) to quite recent (2016). Right-skewed distributions: For both employee count and wages, the mean exceeds the median, suggesting right-skewed distributions with some extremely high values pulling the average up.

Fixing the negative values in number of employees columns

```
[ ]: data.loc[data['no_of_employees'] < 0].shape ## Complete the code to check
      ↪negative values in the employee column
```

```
[ ]: (33, 12)
```

```
[ ]: # taking the absolute values for number of employees
data["no_of_employees"] = abs(data["no_of_employees"]) ## Write the function to
      ↪convert the values to a positive number
```

Let's check the count of each unique category in each of the categorical variables

```
[ ]: # Making a list of all catrgorical variables
cat_col = list(data.select_dtypes("object").columns)
```

```
# Printing number of count of each unique value in each column
for column in cat_col:
    print(data[column].value_counts())
    print("-" * 50)
```

    ) # annotate the percentage

plt.show() # show the plot

```

Observations on education of employee

```
[ ]: labeled_barplot(data, "education_of_employee", perc=True)
```

Observations: Based on this bar chart showing the distribution of education levels among employees, I can make several observations:

Educational distribution: Bachelor's degrees (40.2%) are the most common educational qualification, closely followed by Master's degrees (37.8%). Together, these two categories account for 78% of all employees in the dataset. Advanced education prevalence: The high proportion of employees with Bachelor's, Master's, and Doctorate degrees (combined 86.6%) suggests this dataset likely represents skilled professional positions or knowledge workers. Minimal high school only: Only 13.4% of employees have just a high school education, indicating most positions represented in this data require higher education. Doctorate representation: The smallest category is employees with Doctorate degrees at 8.6%, which is still a substantial percentage for this highest level of formal education. Potential visa context: Given your earlier data exploration showing variables like "continent" and "case_status," this distribution likely represents visa applicants or international workers, who tend to be more highly educated than average.

The educational profile suggests this may be data related to specialized work visas (possibly H-1B

or similar), which typically target highly-skilled workers with advanced degrees.

Observations on region of employment

```
[ ]: labeled_barplot(data, "region_of_employment", perc=True)  ## Complete the code  
    ↳ to create labeled_barplot for region of employment
```

Looking at this bar chart showing the distribution of employment regions, I can make these observations:

Balanced regional distribution: The Northeast (28.2%), South (27.5%), and West (25.8%) regions have fairly similar proportions, each accounting for roughly a quarter of the employment cases. Midwest representation: The Midwest accounts for 16.9% of cases, making it less represented than the other three major continental US regions but still having significant presence. Island scarcity: The “Island” category represents only 1.5% of cases, which is dramatically lower than all other regions. This likely represents territories like Puerto Rico, US Virgin Islands, Guam, or other US-affiliated island territories. Geographical concentration: Collectively, the Northeast, South, and

West regions account for over 81% of all employment cases in the dataset. Potential economic implications: The distribution likely reflects economic activity and job market strength in these regions, with the Northeast, South, and West possibly having more industries that sponsor work visas or employ foreign workers. Possible urban correlation: The regions with higher percentages tend to have more major metropolitan areas and tech hubs, which often employ more foreign workers or visa holders.

This regional distribution provides important context for understanding where these employment cases (likely visa-related) are concentrated throughout the country.

Observations on job experience

```
[ ]: labeled_barplot(data, "has_job_experience", perc=True) ## Complete the code to  
    ↪ create labeled_barplot for job experience
```

Based on this bar chart for “has_job_experience,” I can make these observations:

Experience majority: A clear majority (58.1%) of cases in the dataset involve individuals who have job experience (marked as “Y”). Substantial inexperienced group: A significant portion (41.9%) of cases involve individuals without job experience (marked as “N”). Binary classification: The variable appears to be binary (Yes/No), with no intermediate or other categories. Professional context: This distribution supports the hypothesis that this dataset likely represents visa applications or work permits, where roughly 6 out of 10 applicants have prior job experience. Potential analysis direction:

This variable could be an important factor to explore in relation to case outcomes - whether having experience correlates with higher approval rates for whatever these cases represent.

The relatively high percentage of cases without job experience (41.9%) is notable, suggesting either:

Many entry-level positions being filled Recent graduates applying for positions Special visa categories that may not require prior experience

This would be an important variable to cross-reference with case status and education level in your analysis.

Observations on case status

```
[ ]: labeled_barplot(data, "case_status", perc=True) ## Complete the code to create a  
      ↪ labeled_barplot for case status
```

Based on this bar chart showing the “case_status” distribution, I can make these observations:

Approval dominance: A substantial majority (66.8%) of cases have been “Certified,” indicating approval of the applications. Significant denial rate: About one-third (33.2%) of cases were “Denied,”

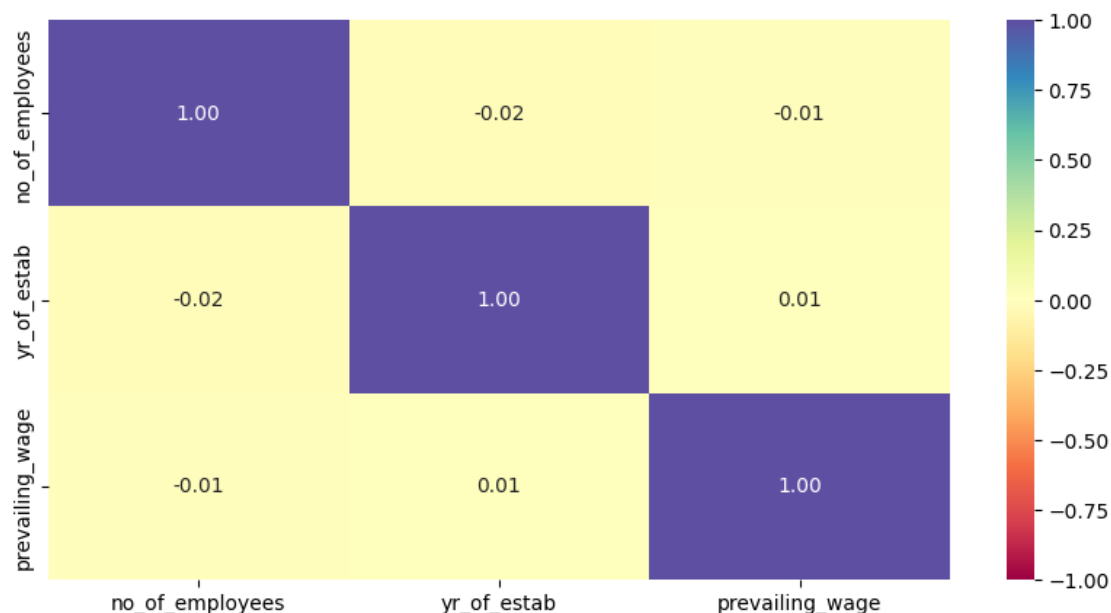

representing a substantial proportion of rejected applications. Binary outcome: The case status appears to be binary (Certified/Denied) with no intermediate categories like “Pending” or “Under Review.” Confirmation of visa context: This chart strongly supports the hypothesis that we’re looking at work visa application data, where “Certified” indicates approval for a work visa or labor certification. Research potential: The significant number of denied cases (33.2%) provides a good balance for analysis - there’s sufficient data in both outcome categories to build meaningful predictive models. Baseline classification performance: This distribution establishes that a naive model always predicting “Certified” would achieve 66.8% accuracy, setting a baseline for any predictive modeling.

This is a key variable in your dataset as it appears to be the target/outcome variable you would want to predict using the other features like education level, job experience, region, etc. The relatively balanced distribution makes this suitable for classification modeling.

0.5.2 Bivariate Analysis

```
[ ]: cols_list = data.select_dtypes(include=np.number).columns.tolist()

plt.figure(figsize=(10, 5))
sns.heatmap(
    data[cols_list].corr(), annot=True, vmin=-1, vmax=1, fmt=".2f",
    cmap="Spectral"
) ## Complete the code to find the correlation between the variables
plt.show()
```

Looking at this correlation heatmap for the three numeric variables in your dataset, I observe:

No significant correlations between variables: The correlations between the different pairs of vari-

ables are extremely weak:

Number of employees and year of establishment: -0.02 (negligible negative correlation) Number of employees and prevailing wage: -0.01 (negligible negative correlation) Year of establishment and prevailing wage: 0.01 (negligible positive correlation)

Variable independence: These near-zero correlations suggest that the three numeric variables are essentially independent of each other, with no meaningful linear relationships. Modeling implications:

Company size doesn't correlate with company age Wages offered aren't meaningfully related to company size or age Each variable provides unique information that isn't captured by the others

Analysis direction: Since these numeric variables don't show relationships with each other, it will be important to examine how each one individually relates to the case outcome (Certified/Denied).

Feature selection: The independence of these variables is actually beneficial for modeling, as they won't introduce multicollinearity issues if used together in predictive models.

The lack of correlation means you can treat each of these numeric features as providing separate, non-redundant information about the cases in your dataset.

Creating functions that will help us with further analysis.

```
[ ]: ### function to plot distributions wrt target

def distribution_plot_wrt_target(data, predictor, target):

    fig, axs = plt.subplots(2, 2, figsize=(12, 10))

    target_uniq = data[target].unique()

    axs[0, 0].set_title("Distribution of target for target=" +
↪str(target_uniq[0]))

    data: dataframe
    predictor: independent variable
    target: target variable
    """
    count = data[predictor].nunique()
    sorter = data[target].value_counts().index[-1]
    tab1 = pd.crosstab(data[predictor], data[target], margins=True).sort_values(
        by=sorter, ascending=False
    )
    print(tab1)
    print("-" * 120)
    tab = pd.crosstab(data[predictor], data[target], normalize="index").
↪sort_values(
        by=sorter, ascending=False
    )
    tab.plot(kind="bar", stacked=True, figsize=(count + 5, 5))
    plt.legend(
        loc="lower left", frameon=False,
    )
    plt.legend(loc="upper left", bbox_to_anchor=(1, 1))
    plt.show()

```

Those with higher education may want to travel abroad for a well-paid job. Let's find out if education has any impact on visa certification

```
[ ]: stacked_barplot(data, "education_of_employee", "case_status")
```

case_status	Certified	Denied	All
education_of_employee			
All	17018	8462	25480
Bachelor's	6367	3867	10234
High School	1164	2256	3420
Master's	7575	2059	9634
Doctorate	1912	280	2192

Looking at both the chart and the provided data table, I can make several significant observations about the relationship between education level and visa certification outcomes:

Strong positive correlation between education and approval rates:

Doctorate: 87.2% approval rate (1,912 certified out of 2,192) Master's: 78.6% approval rate (7,575 certified out of 9,634) Bachelor's: 62.2% approval rate (6,367 certified out of 10,234) High School: 34.0% approval rate (1,164 certified out of 3,420)

Dramatic education advantage: The approval rate for those with doctorate degrees (87.2%) is more than 2.5 times higher than for those with only high school education (34%). Reversal of odds: High school education is the only category where denials exceed certifications (66% denial rate), while all higher education levels show more certifications than denials. Incremental benefits: Each step up in educational attainment shows a substantial improvement in approval chances, with

approximately 15-20 percentage point increases between adjacent education levels. Advanced degree preference: Master's and Doctorate degrees combined have a 79.8% approval rate (9,487 certified out of 11,826), suggesting a strong preference for advanced degree holders. Policy implications: This data strongly suggests that immigration/visa policies strongly favor higher educational attainment, possibly indicating a focus on attracting highly skilled workers. Value of education investment: For potential visa applicants, this data demonstrates a clear return on educational investment in terms of improved visa approval chances.

This analysis confirms that education level is a major factor in visa certification outcomes, with higher education significantly improving approval chances.

Lets' similarly check for the continents and find out how the visa status vary across different continents.

```
[ ]: stacked_barplot(data, "continent", "case_status") ## Complete the code to plot
      ↪ stacked barplot for region of continent and case status
```

case_status	Certified	Denied	All
continent			
All	17018	8462	25480
Asia	11012	5849	16861
North America	2037	1255	3292
Europe	2957	775	3732
South America	493	359	852
Africa	397	154	551
Oceania	122	70	192

Experienced professionals might look abroad for opportunities to improve their lifestyles and career development. Let's see if having work experience has any influence over visa certification

```
[ ]: stacked_barplot(data, "region_of_employment", "has_job_experience") ## Complete
      ↳ the code to plot stacked barplot for region of case_status and
      ↳ has_job_experience
```

has_job_experience	N	Y	All
region_of_employment			
All	10678	14802	25480
Northeast	2934	4261	7195
South	2920	4097	7017
West	2705	3881	6586
Midwest	1964	2343	4307
Island	155	220	375

Looking at the stacked bar chart and the accompanying data table, I can make these observations about the relationship between job experience and regional distribution:

Similar regional distributions: The proportional distribution of regions appears remarkably consistent between those with job experience (Y) and those without (N). This suggests that experience level doesn't strongly influence which region candidates apply to work in. Regional consistency regardless of experience:

Northeast represents about 28-29% of applications in both experience categories South represents about 27-28% of applications in both categories West represents about 25-26% of applications

in both categories Midwest represents about 16-18% of applications in both categories Islands represent about 1.5% of applications in both categories

Experience rates within regions:

Island: 58.7% with experience (220 out of 375) Midwest: 54.4% with experience (2,343 out of 4,307) Northeast: 59.2% with experience (4,261 out of 7,195) South: 58.4% with experience (4,097 out of 7,017) West: 58.9% with experience (3,881 out of 6,586)

Regional uniformity in experience levels: All regions show a relatively similar proportion of experienced vs. non-experienced applicants (54-59% experienced), with the Midwest having a slightly lower proportion of experienced applicants. Limited regional selection bias: The data doesn't show strong evidence that experienced professionals target specific regions significantly more than in-experienced ones. This suggests that other factors (such as job availability, industry clusters, or personal connections) may be more important in determining regional application patterns.

This visualization indicates that while job experience is an important factor in visa certification overall (as we saw in previous charts), the regional distribution of applications is quite consistent regardless of experience level. The slightly lower experience percentage in the Midwest might be worth investigating further.

Checking if the prevailing wage is similar across all the regions of the US

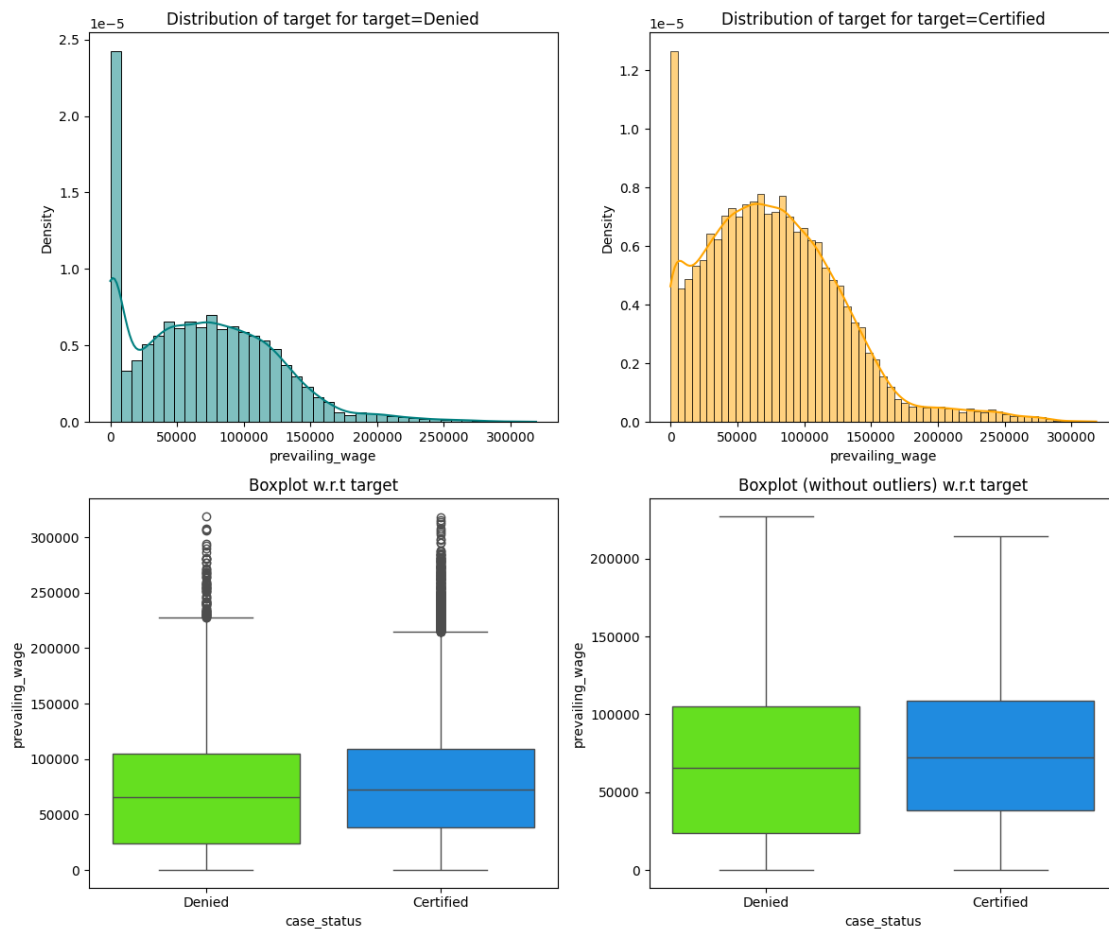

```
[ ]: plt.figure(figsize=(10, 5))
sns.boxplot(x='region_of_employment', y='prevailing_wage', data=data) ##
    ↪ Complete the code to create boxplot for region of employment and prevailing
    ↪ wage
plt.show()
```

The US government has established a prevailing wage to protect local talent and foreign workers. Let's analyze the data and see if the visa status changes with the

prevailing wage

```
[ ]: distribution_plot_wrt_target(data, "prevailing_wage", "case_status") ##_
    ↪ Complete the code to find distribution of prevailing wage and case status
```

Based on the visualizations examining the relationship between prevailing wage and visa case status (Certified vs. Denied), I can make these observations:

Different wage distributions: The density plots (top row) show distinctly different wage distributions between denied and certified cases:

Denied cases (left) show a prominent spike at very low wages (near \$0) and a secondary distribution centered around \$50,000-\$100,000. Certified cases (right) show a more normal distribution centered around \$60,000-\$80,000, with fewer cases at extremely low wages.

Bimodal denied distribution: The denied cases exhibit a bimodal distribution with peaks at very low wages and mid-range wages, suggesting two different categories of denied applications.

Higher median for certified cases: The boxplots indicate that certified cases have a slightly higher median wage compared to denied cases, though the difference doesn't appear dramatic.

Similar wage ranges after outlier removal: When outliers are removed (bottom right), both certified and denied cases show similar wage ranges, suggesting that extreme wage values aren't the primary determinant

of case outcomes. High-wage outliers in both categories: Both categories show high-wage outliers extending to around \$300,000 (visible in bottom left boxplot), indicating that even high-wage applications can be denied. Policy implications: The data suggests that very low-wage applications have higher denial rates, which aligns with the U.S. government's stated goal of protecting both local talent and foreign workers from wage suppression. Not a deterministic factor: While wage appears to influence certification outcomes (particularly at the lowest wage levels), the substantial overlap in distributions indicates that wage alone is not deterministic - other factors clearly play important roles in the certification decision.

This analysis suggests that while extremely low-wage applications face higher denial rates, prevailing wage is just one of several factors considered in visa applications, with many mid-to-high wage applications still being denied for other reasons.

The prevailing wage has different units (Hourly, Weekly, etc). Let's find out if it has any impact on visa applications getting certified.

```
[ ]: stacked_barplot(data, "unit_of_wage", "case_status") ## Complete the code to
      ↪ plot stacked barplot for unit of wage and case status
```

case_status	Certified	Denied	All
unit_of_wage			
All	17018	8462	25480
Year	16047	6915	22962
Hour	747	1410	2157
Week	169	103	272
Month	55	34	89

0.6 Data Pre-processing

0.6.1 Outlier Check

- Let's check for outliers in the data.

```
[ ]: # outlier detection using boxplot
numeric_columns = data.select_dtypes(include=np.number).columns.tolist()

plt.figure(figsize=(15, 12))

for i, variable in enumerate(numeric_columns):
    plt.subplot(4, 4, i + 1)
    plt.boxplot(data[variable], whis=1.5)
    plt.tight_layout()
    plt.title(variable)

plt.show()
```

0.6.2 Data Preparation for modeling

- We want to predict which visa will be certified.
- Before we proceed to build a model, we'll have to encode categorical features.
- We'll split the data into train and test to be able to evaluate the model that we build on the train data.

```
[ ]: data["case_status"] = data["case_status"].apply(lambda x: 1 if x == "Certified"
↪ else 0)

X = data.drop(["case_status"], axis=1) ## Complete the code to drop case status
↪ from the data
y = data["case_status"]

```

0.7 Model Building

0.7.1 Model Evaluation Criterion

Provide some reasoning for choosing the metric here : _____

First, let's create functions to calculate different metrics and confusion matrix so that we don't have to use the same code repeatedly for each model. * The `model_performance_classification_sklearn` function will be used to check the model performance of models. * The `confusion_matrix_sklearn` function will be used to plot the confusion matrix.

```
[ ]: # defining a function to compute different metrics to check performance of a  
↪classification model built using sklearn  
  
def model_performance_classification_sklearn(model, predictors, target):  
    """  
        Function to compute different metrics to check classification model  
↪performance  
  
        model: classifier  
predictors: independent variables  
target: dependent variable  
    """  
  
    # predicting using the independent variables  
    pred = model.predict(predictors)  
  
    acc = accuracy_score(target, pred) # to compute Accuracy  
    recall = recall_score(target, pred) # to compute Recall  
    precision = precision_score(target, pred) # to compute Precision  
    f1 = f1_score(target, pred) # to compute F1-score  
  
    # creating a dataframe of metrics  
    df_perf = pd.DataFrame(  
        {"Accuracy": acc, "Recall": recall, "Precision": precision, "F1": f1},  
        index=[0],  
    )  
  
    return df_perf
```

```
[ ]: def confusion_matrix_sklearn(model, predictors, target):  
    """  
        To plot the confusion_matrix with percentages  
  
        model: classifier  
predictors: independent variables  
target: dependent variable  
    """
```

```

y_pred = model.predict(predictors)
cm = confusion_matrix(target, y_pred)
labels = np.asarray(
    [
        ["{0:0.0f}".format(item) + "\n{0:.2%}".format(item / cm.flatten().
↪sum())]
        for item in cm.flatten()
    ]
).reshape(2, 2)

plt.figure(figsize=(6, 4))
sns.heatmap(cm, annot=labels, fmt="")
plt.ylabel("True label")
plt.xlabel("Predicted label")

```

Defining scorer to be used for cross-validation and hyperparameter tuning

```

[ ]: scorer = metrics.make_scorer(metrics.f1_score) ## Complete the code to define
↪the metric

## Possible metrics are [recall_score, f1_score, accuracy_score, precision_score]
## For example, metrics.precision_score

```

We are now done with pre-processing and evaluation criterion, so let's start building the model.

0.7.2 Model building with original data
